CFD methods have made it possible to simulate some of the most delicate flow behaviors that are important to understanding industrial and environmental processes. In this post, we will take a brief look at two of the most common methods used to simulate multiphase flows in manufacturing processes: dispersion modeling and multiphase flow simulation. The three-phase simulation is the multiphase flow approach that is now the most widely used in the CFD community. The reason for this is that it has a fundamental advantage over the two-phase method, namely that it can simulate flows in which the three phases are present at the same time, making it possible to model non-separated systems. For small Reynolds number flows, where viscous forces are dominant, the Couette flow problem is similar to the settling of a particle. In the free surface flow, the boundary layer on the free surface of the liquid behaves like an impervious surface and the flow becomes “sharp”. A typical dimensionless velocity is called the dimensionless velocity of sharpness, u*. Eulerian Multiphase Granular.zip The model considers a d-dimensional straight pipe and the fluid flows in a quasi-steady state. The flow is characterized by dimensionless velocity u* based on the pipe diameter D, the density ρ and the velocity of the carrier fluid U. The Eulerian-Granular model uses an Eulerian approach and a level-set approach to deal with the contact line. It is worth noting that the dimensionless velocity of sharpness could be up to two orders of magnitude larger than that corresponding to dimensional analysis.

Eulerian Multiphase Granular.zip

Hi, I have an Eulerian-Granular model: a Liquid droplet embedded in the wall of a Liquid; the volume of the droplet is changing through time due to evaporation. I have the following questions: I want to calculate the volume of the droplet to show how it changes with time. Could you explain how to calculate it? I want to show the volume of the droplet and its evaporation rate (evaporation rate = change in volume/time). Would you be so kind to give me some pointers on how to do so? I have also read a more advanced blog post on granular flow. It concerns the properties of a solid particle after it has been compressed into a pellet. If I understand that correctly, the lower it is, the less resistance the fluid has and the lower its viscosity. I would appreciate it if you could explain to me how this could be modelled. Hi, Thank you for your interest in the Eulerian-Granular two-phase system you were talking about. After a good number of research, I found this nice publication which was published while I was studying this problem. (Granular two-phase system) Thanks again. To the best of my knowledge, there is no out of box Eulerian-Granular two phase model available in COMSOL Multiphysics. This is because it is not clear how to set up the model on the ‘Eulerian’ side or how to set up the model on the ‘Granular’ side. Please can you help me to understand how this can be done and possibly point me to some documentation which will help with this process. The fact is that the droplet boundaries are not fixed point boundaries. 5ec8ef588b
