Phenothiazine-type drugs as anti-viral agents: their role in combination therapy for AIDS.

The anti-viral activity of various phenothiazine-type drugs was evaluated against several viruses, in particular those causing human immunodeficiency virus (HIV)-related illnesses. These studies revealed that phenothiazine-type drugs exhibit significant antiviral activity against HIV-1 and -2. In addition, we have evaluated the effects of in vitro exposure to these anti-viral compounds on the growth of B-lineage HIV-1 infected peripheral blood mononuclear cells (PBMC) in culture. Growth of B-lineage HIV-1 and HIV-2 was not affected by concentrations of phenothiazine-type drugs that were in excess of 1 microM. However, the growth of T-lineage HIV-1-infected cells was strongly inhibited by phenothiazines which were inactive against B-lineage virus. These data indicate that patients with AIDS who are being treated with phenothiazine-type drugs can be expected to be less susceptible to certain opportunistic infections than untreated patients. The data also reveal that treatment of individuals harboring B-lineage HIV-1 may be ineffective. The clinical significance of these observations awaits the outcome of ongoing clinical trials with phenothiazine-type drugs.
