The pseudo-tetrahedron C1/C2 is the most stable structure in water. Its four-membered ring has the smallest mean distance to the closest oxygen of the water molecules. The C3/C4 tetrahedron is the most stable structure in gas phase. In solution, the most stable tetragonal configuration, where C3 is connected to C4, is not the lowest in energy (Table 1)(#T1){ref-type="table"}, but an asymmetric, distorted configuration, where C3 and C4 are not congruent (Table 1)(#T1){ref-type="table"}). The most stable configuration is the one where C1 and C4 are connected. The last two configurations are not connected to each other and to the transition state. This means that they are absent in the transition state in solution. The configuration C3 is likely to be absent in the transition state (in solution). Although the space available for the transformation is significant (Figure 2)(#F2){ref-type="fig"}, the energy difference between the transition state and the isomer C1 is very small (9 kcal
