The Monte Cristo mainshock is being applied in studies by many different groups. Some of these groups have similar goals, such as determining the amount of crystalline rock that was affected by the mainshock, but the methods they use differ. The UT-Dallas group has been able to generate 3D geological models of the sub-glacial region using measurements from the site aftershocks, and especially from GPS. (see Cumulative GPS sites around Monte Cristo). In addition to the GPS site, other methods have been used at the precise locations of infrasound sources. The UT-Dallas group will also attempt to apply the method of Fourier analysis that is used to study signals in the crust due to Earthquake. Results from this work will be provided to the oil and gas industry. Monte Cristo is part of a group of dynamic and challenging real-time strategy games that use the well-received and well-proven game engine and features from RTS series such as

Dawn of War, Warcraft III, and Company of Heroes. Monte Cristo is a real-time strategy game where two opposing generals fight for control of the Atlantic and the European fronts during World War II. Players control a battalion of soldiers and can even form their own special units, such as the famous flamethrower crews. The game can be played by two or four players. Soils in the southern Mina Deflection are generally derived from layers of volcanic and sedimentary deposits (Wagner et al. 1994 ; Stewart and Flemming 2002 ; Rueda et al. 2015) and vary in thickness from 50 to 2000 m. Soils of the Monte Cristo Range are coarse-textured and high in exchangeable bases, derived from diatom- and algal-dominated marine and lacustrine sedimentation. The middle to upper midland terraces are identified by porous friable alluvial deposits and contain the Mesaverde Group, a Miocene-aged band of sandstone to quartzite (Stander 1986 ; Stander and Wagner et al. 1989 ; Wagner and Chapman et al. 2002). However, the extent, age, and depth of surficial deposits vary by as much as ~3600 m from

point to point and this variability is a key factor to the interpretation of the seismic moment release (M_w) and slip distribution of the Monte Cristo Range and southern CSMB earthquakes of May 2015 and January 2020 (Kerstetter 2017a ; Kerstetter 2017b). The number of patches and their fault segments also affect the complexity of the Monte Cristo Range N-S faulting (i.e., whether a maximum M_w will be reached or can be achieved with fewer faults; Wild et al. 2010). 5ec8ef588b
